

# Crypto for PETs – Part 3

Jorge Cuellar

WS 18-19

# Processing data securely in the Cloud

Assume that a "client" is working in a cloud ("server")

- ▶ and some data fields are numbers (sensitive values)
  - ▶ say, amounts of money in Euro
  - ▶ they must be maintained encrypted
    - ▶ so that the cloud provider (the server) or any other in the cloud
    - ▶ is not able to read the cleartext

But the client wants to *process the data in the cloud*

- ▶ That means: upload a program to the cloud,
  - ▶ do the arithmetic processing there
  - ▶ fetch back the data
    - ▶ and — only then — decrypt it

Is it possible to "calculate with encrypted data"?

# Homomorphic Encryption

## Homomorphic encryption

allows

- ▶ addition and/or multiplication
- ▶ to be carried out on the encrypted values
  - ▶ when the result is decrypted, it yields the same result
  - ▶ as the same calculation on the unencrypted inputs:
- ▶  $\mathcal{D}(\mathcal{E}(v_1) \circ \mathcal{E}(v_2)) = (v_1 \circ v_2)$

In other words,

- ▶  $(\mathcal{E}(v_1) \circ \mathcal{E}(v_2))$  is one encryption of  $(v_1 \circ v_2)$

## Fully-homomorphic encryption (for both, addition and mult)

- ▶ is ongoing research

# Recall: RSA with public parameter $n = p \cdot q$

$p, q$ : two random secret primes

- ▶  $d$ : the *public key* is a random number:  $1 < d < n - 1$
- ▶  $e$ : the *private key* is a number with:  $d \cdot e \equiv_{(p-1)(q-1)} 1$

Message  $m$  is encrypted as

- ▶  $\mathcal{E}(m) := m^e \in \mathbb{Z}_n^*$

and  $c = \mathcal{E}(m)$  is decrypted via

- ▶  $D(c) := c^d \in \mathbb{Z}_n^*$

# Homomorphic Encryption

## RSA is multiplicatively homomorphic:

If you encrypt two numbers separately,

- ▶ using the same secret key,
  - ▶ multiply the ciphertexts, then decrypt the result,
- ▶ you get the same result that you would get
  - ▶ if you multiplied the two original numbers

But RSA is not homomorphic for addition

# Homomorphic Encryption

## RSA is Multiplicatively Homomorphic

RSA is multiplicative homomorphic:

$$\blacktriangleright \mathcal{E}(m_1) \cdot \mathcal{E}(m_2) = \mathcal{E}(m_1 \cdot m_2)$$

Given

$$\blacktriangleright c_i = \mathcal{E}(m_i) = m_i^e \text{ mod } N$$

$$c_1 = m_1^e \text{ mod } N$$

$$c_2 = m_2^e \text{ mod } N$$

$$c_1 \cdot c_2 = m_1^e \cdot m_2^e \text{ mod } N$$

$$= (m_1 \cdot m_2)^e \text{ mod } N$$

# Homomorphic encryption for Aggregation

Homomorphic cryptosystems are used to create aggregated data

- ▶ calculate some statistics (averages, sums, etc) on personal data
  - ▶ that hide (in some cases) the values of the sensitive personal data

Homomorphic encryption can be used

- ▶ for example secure voting systems
- ▶ for private information retrieval schemes
- ▶ and many more

# El Gamal Encryption

Public parameters:

- ▶  $G$ , a group,
- ▶  $|G|$ , the order of the group,
- ▶  $g$ , a generator of  $G$

The public key is

- ▶  $PK = g^{pk} \in G$  for some secret private key  $pk \in \{1, \dots, |G| - 1\}$

To encrypt a message  $m \in G$ ,

- ▶ generate a random  $x \in \{1, \dots, |G|\}$
- ▶  $\mathcal{E}(m) := (g^x, PK^x \cdot m)$

# El Gamal is a homomorphic encryption

Given encryptions

- ▶  $\mathcal{E}(m_1) = (g^{x_1}, PK^{x_1} \cdot m_1)$

- ▶  $\mathcal{E}(m_2) = (g^{x_2}, PK^{x_2} \cdot m_2)$

Then the pointwise product of those two encrypted messages

- ▶  $\mathcal{E}(m_1) \cdot \mathcal{E}(m_2) =$

- ▶  $(g^{x_1}, PK^{x_1} \cdot m_1) \cdot (g^{x_2}, PK^{x_2} \cdot m_2) :=$

- ▶  $(g^{x_1} \cdot g^{x_2}, PK^{x_1} \cdot m_1 \cdot PK^{x_2} \cdot m_2)$

- ▶ is an encryption of the product  $(m_1) \cdot (m_2)$

Proof:

- ▶ If we multiply two messages componentwise, we get

$$(g^{x_1}, PK^{x_1} \cdot m_1) \cdot (g^{x_2}, PK^{x_2} \cdot m_2) = (g^{x_1+x_2}, PK^{x_1+x_2} \cdot m_1 \cdot m_2) = (g^x, PK^x \cdot (m_1 \cdot m_2))$$

El Gamal is homomorphic with respect to multiplication

# Oblivious Transfer

An oblivious transfer protocol (OT)

- ▶ is a type of query-response protocol

The "client" or "**receiver**" asks for a piece of information

- ▶ say: an entry of a DB

The "server" or "**sender**" responds with the information

- ▶ or with nothing
  - ▶ BUT: he remains oblivious (= unaware, unconscious) about
    - ▶ the content of the query
    - ▶ what piece (if any) has been transferred

In some variants of OT

- ▶ it is not a query-response protocol
  - ▶ simply a "send" protocol
- ▶ where a sender transfers one of
  - ▶ piece of information to a receiver out of a set
    - ▶ without knowing which one

# 1-2 Oblivious Transfer

Recall first D-H:

- ▶  $A$  chooses  $a \leftarrow \mathbb{Z}_p$ ,  $A = g^a$
- ▶  $B$  chooses  $b \leftarrow \mathbb{Z}_p$ ,  $B = g^b$

$$A \xrightarrow{A} B$$

$$A \xleftarrow{B} B$$

$$A \xrightarrow{e \leftarrow E_k(m)} B$$

Where  $E_k$  is encryption with the key  $k$  known to both:  $k = B^a = A^b$

- ▶ Observe that Alice can also derive
  - ▶  $\widehat{B}^a = \left(\frac{B}{A}\right)^a$ 
    - ▶ but Bob cannot compute it this group element (assuming CDH)

# 1-2 Oblivious Transfer

Consider the following D-H variant:

- ▶  $A$  chooses  $a \leftarrow \mathbb{Z}_p$ ,  $A = g^a$
- ▶  $B$  chooses  $b \leftarrow \mathbb{Z}_p$ ,  $B = g^b$

$$A \xrightarrow{A} B$$

$$A \xleftarrow{\tilde{B}=AB} B$$

$$A \xrightarrow{e \leftarrow E_k(m)} B$$

Where  $E_k$  is encryption with the key  $k$  known to both:

- ▶  $k = \left(\frac{\tilde{B}}{A}\right)^a = \left(\frac{AB}{A}\right)^a = A^b$

# Oblivious Transfer

- ▶  $A$  has two messages  $m_0, m_1$
- ▶  $B$  wants message  $i$
- ▶ As above
  - ▶  $A$  chooses  $a \leftarrow \mathbb{Z}_p, A = g^a$
  - ▶  $B$  chooses  $b \leftarrow \mathbb{Z}_p, B = g^b$

Depending on  $i$ , in the second message,  $B$  either sends

- ▶  $\tilde{B} = B$  if  $c = 0$  or
- ▶  $\tilde{B} = AB$  if  $c = 1$

Now  $A$  calculates both

- ▶  $k_0 = (\tilde{B})^a$
- ▶  $k_1 = (\frac{\tilde{B}}{A})^a$

and sends both  $e_0 \leftarrow E_{k_0}(m_0)$  and  $e_1 \leftarrow E_{k_1}(m_1)$

# Threshold Decryption and Threshold Signatures

- ▶ A threshold public key encryption system is a
  - ▶ public key system where the private key is
    - ▶ distributed among  $n$  decryption servers so that
    - ▶ at least  $k$  servers are needed for decryption
- ▶ In a threshold encryption system an entity
  - ▶ called the **combiner**
    - ▶ has a ciphertext  $c$  that it wishes to decrypt
- ▶ The combiner sends  $c$  to the decryption servers
  - ▶ and receives partial **decryption shares**
    - ▶ from at least  $k$  out of the  $n$  decryption servers
- ▶ It then combines these  $k$  partial decryptions
  - ▶ into a complete decryption of  $c$
- ▶ Ideally, there is no other interaction in the system
  - ▶ namely the servers need not talk to each other during decryption
- ▶ Such threshold systems are called non-interactive

# Dining cryptographers

- ▶ David Chaum proposed 1988 the Dining cryptographers
  - ▶ showing it is possible to send anonymous messages with
    - ▶ unconditional sender and recipient untraceability
- ▶ Cryptographers  $A_i$  for  $i = 1, 2, \dots, n$  around a table for dinner
  - ▶  $A_i$  has a secret  $s_i$
- ▶ Collectively they want to calculate
  - ▶  $s_1 \oplus s_2 \oplus \dots \oplus s_i \dots \oplus s_n$
  - ▶  $\sum_i s_i \pmod{2}$

# Dining cryptographers, "Toy Use Case":

- ▶ The waiter informs them that the meal
  - ▶ has been paid for by someone
    - ▶ who could be one of the cryptographers or their boss
- ▶ The cryptographers respect each other's right to
  - ▶ make an anonymous payment
    - ▶ but want to find out whether the boss paid
    - ▶ (The boss has no privacy right here)

# Dining cryptographers

- ▶ Notice that each cryptographer has a secret  $s_i$ 
  - ▶ which is 1 if he paid for the meal and 0 else
- ▶ So they decide to execute a two-stage protocol
- ▶ In the first phase
  - ▶ Each two cryptographers  $A_i, A_{i+1}$  sitting next to each other
    - ▶ establish a shared random one-bit secret  $b_{i,i+1}$
    - ▶ so that only those two cryptographers know the outcome
  - ▶ Example with 3 cryptographers:
    - ▶  $A_1, A_2$  share secret  $b_{1,2} = 1$
    - ▶  $A_2, A_3$  share  $b_{2,3} = 0$
    - ▶  $A_3, A_1$  share  $b_{3,4} = 1$

# Dining cryptographers: one solution

- ▶ Now each cryptographer
  - ▶ publicly announces the bit
    - ▶  $a_i = s_i \oplus b_{i,i-1} \oplus b_{i,i+1}$
    - ▶ where  $i - 1, i + 1$  are mod  $n$

Then  $\sum_i s_i = \sum_i a_i$ , because in the second sum

- ▶ each of the numbers  $b_{i,i-1}$  appears twice (in  $a_i$  and in  $a_{i+1}$ )
  - ▶ and therefore cancel out

Thus the sum  $\sum_i a_i$  reveals if one of the  $s_i$  is one

- ▶ That is, one of the cryptographers paid

# Dining cryptographers: one solution

- ▶ In other words
  - ▶ if  $A_i$  didn't pay for the meal
    - ▶ he shows the xor of
      - ▶ the two shared bits he holds with his neighbours
  - ▶ if he did pay for the meal
    - ▶ the opposite of that xor
- ▶ In the example (above)
  - ▶ if none of the cryptographers paid, then
    - ▶  $A_1$  would announce  $b_1 = 0 \oplus 1 \oplus 0 = 1$ ,
    - ▶  $A_2$  would announce  $b_2 = 0 \oplus 1 \oplus 1 = 0$ , and
    - ▶  $A_3$  would announce  $b_3 = 0 \oplus 0 \oplus 1 = 1$
- ▶ On the other hand
  - ▶ if  $A_1$  paid, he would announce
    - ▶  $b_2 = 1 \oplus 1 \oplus 1 = 1$

# Dining cryptographers: one solution

- ▶ Notice that the xor of
  - ▶ all the announced bits  $b_i$  is 0
    - ▶ iff none of the cryptographers paid
    - ▶ so the boss must have paid
- ▶ Otherwise if the xor of
  - ▶ all the announced bits  $b_i$  is 1
    - ▶ then one of the cryptographers paid
    - ▶ but his identity remains unknown
    - ▶ to anybody, including the other cryptographers
- ▶ Anonymous communication networks
  - ▶ based on this problem are often known as DC-nets

# Secure Multi-Party Computations

Assume  $n$  parties  $P_1, \dots, P_n$

- ▶ each one in possession of a (secret) value  $x_i$

The parties want to calculate a set of functions

- ▶  $\tilde{f}(\bar{x}) = f_1(x_1, \dots, x_n, r), \dots, f_n(x_1, \dots, x_n, r)$  with  $r \leftarrow \mathcal{D}$ 
  - ▶ over their data,  $(x_1, \dots, x_n)$ ,
  - ▶ plus perhaps a (common) random input  $r$ , with:

## Requirements

- ▶ Party  $P_i$  should learn the result  $f_i(x_1, \dots, x_n, r)$  and
  - ▶ should learn nothing else
- ▶ No external to the protocol (eavesdropper)
  - ▶ should learn anything
- ▶ This should hold even
  - ▶ if an arbitrary subset of the parties maliciously deviates from the protocol

# Secure Multi-Party Computations

This can be easily done if the parties have

- ▶ direct, unrestricted and **secure** access to an
  - ▶ "angelic" trusted third party (T3P)

Then: each party  $P_i$  sends the input  $x_i$  to the T3P

- ▶ over an ideal secure channel
  - ▶ no one can read or modify this value

The T3P computes  $y_1 = f_1(x_1, \dots, x_n, r), \dots, y_n = f_n(x_1, \dots, x_n, r)$

- ▶ sends  $y_i$  to  $P_i$ 
  - ▶ (over the secure channel)

# Secure Multi-Party Computations

Secure multi-party computations do the same thing

- ▶ but not relying on a third party
  - ▶ but rather only on cryptographical methods

Def: a protocol  $\pi$  securely realizes  $\bar{f}(\bar{x})$  if

running  $\pi$  emulates

- ▶ an ideal process where
  - ▶ all parties secretly provide inputs to a trusted party
  - ▶ which computes  $\bar{f}$  and returns the outputs to the parties
- ▶ and any "harm" done by a ppt adversary
  - ▶ in the real execution of  $\pi$
- ▶ could have been done by
  - ▶ a ppt in the ideal process

# Secure Multi-Party Computations

- ▶ The T3P solution provides not only security against individual cheaters
  - ▶ also ensures security if several parties are colluding throughout the entire execution
  - ▶ If some set  $B$  of parties collude
  - ▶ then the parties in that set learn the union of what they each learn individually
  - ▶ but nothing more
- ▶ The solution using a trusted party is "the best one could hope for"
  - ▶ (if the T3P is really trustworthy)
  - ▶ and we will therefore take this as our "ideal world"
- ▶ In the real world, in contrast
  - ▶ there may not exist any trusted parties that all the players agree upon

# Secure Multi-Party Computations

- ▶ Protocols for secure computation should provide a way for
- ▶  $P_1, \dots, P_n$  to achieve the security guarantees of the ideal world without the T3P
- ▶ Roughly speaking
  - ▶ a protocol is "secure" if the actions of any colluding parties in the real world can be emulated by those same parties in the ideal world
- ▶ But let us generalize the model a bit by introducing randomness and introducing a "*don't care*" notion

# Secure Multi-Party Computations

- ▶ The concept of Secure Multi-Party Computation generalizes
  - ▶ confidentiality and integrity of data

## Example/Exercise

Describe the problem of

- ▶ secure (confidentiality and integrity protected) communication
  - ▶ from  $P_1$  to  $P_2$

as a MPC problem of computing the function  $f_?(x?) = x?$

# Secure Multi-Party Computations

Recall we have  $n$  parties

- ▶ each one in possession of a (secret) value  $x_i$

They want to calculate

- ▶  $f_1(x_1, \dots, x_n, r), \dots, f_n(x_1, \dots, x_n, r)$  with  $r \leftarrow \mathcal{D}$ 
  - ▶ (with some additional random input  $r$ )
- ▶ and party  $i$  gets exactly the result of  $f_i$

Shorthand  $F(x_1, x_2, \dots, x_n) :=$

$(f_1(x_1, x_2, \dots, x_n, r), \dots, f_n(x_1, x_2, \dots, x_n, r))$

- ▶  $F$  is the function that
  - ▶ takes all the inputs from all parties and
  - ▶ calculates all the outputs for them

- ▶ Info (Remark:  $F$  is non-deterministic, while each  $f_i$  is)

# Secure Multi-Party Computations

- ▶ The concept of Secure Multi-Party Computation is
  - ▶ very general and
  - ▶ very strong

## Examples

- ▶  $F(x_1, \dots, x_n) = x_1 + \dots + x_n$  a simple sum function
  - ▶ where all parties get the same value
- ▶  $F(x_1, \dots, x_n) = \text{MAX}(x_1, \dots, x_n)$  a max-value function
- ▶  $F(-, \dots, -) = r \leftarrow \mathcal{D}$  a simple coin toss function
  - ▶ Here the main requirement is that the output remains unbiased in spite of any malicious behavior

# Secure Multi-Party Computations

## Examples

- ▶  $F((x_0, x_1), b) = (-, x_b(b \leftarrow \{0, 1\}))$ 
  - ▶ This is 1-of-2 oblivious transfer:
  - ▶ Party 2 learns one of two values that party 1 had
  - ▶ and party 1 doesn't know which value party 2 learned
- ▶  $F_R((x, w), -) = (-, (x, R(x, w)))$  where  $R(x, w)$  is a binary relation
  - ▶ This is a modelling of Zero-Knowledge (we have correctness and soundness)
  - ▶ This is also a proof of knowledge of a witness

# MPC Yao's Garbled Circuits

Assume parties  $P_1$  and  $P_2$  share a Boolean Circuit  $f_c$  for  $f = (f_1, f_2)$

- ▶ With inputs  $i_1$  that will be provided by  $P_1$  and
- ▶  $i_2$  to be provided by  $P_2$

This circuit is in "cleartext":

- ▶ It has a finite number of wires  $w_1, w_2, \dots$  and gates  $g_1, g_2 \dots$ 
  - ▶ Each gate  $g_i$  is given by a "truth table" on three wires
- ▶ In a moment we will explain
  - ▶ how wires and gates can be "garbled",
    - ▶ constructing a "garbled circuit"
  - ▶ how to evaluate a "garbled circuit":
    - ▶ given garbled wire values
    - ▶ how to calculate the garbled output wire

The high-level view of Yao's construction is given in the next slide

# MPC Yao's Garbled Circuits, Overview

1.  $P1$  garbles each **wire** and each **gate** of the clear-text circuit  $f_c$ 
  - ▶ except the output bits of  $f_2$
  - ▶ creating garbled circuit  $f_g$
2.  $P1$  sends  $f_g$  and the garbled values for his inputs  $i_1$
3.  $P2$  uses  $OT$  to get the garbled values of his inputs  $i_2$  in  $f_g$
4.  $P2$  calculates  $f_g$  with the garbled versions of  $i_1$  and  $i_2$ 
  - ▶ obtains his output  $f_1$  and sends to  $P1$  the garbled values for  $f_2$

# MPC A Circuit in Cleartext

Where the gates are given by tables, i.e for  $G_3$  (an or-gate):

$w_5$	$w_6$	$w_7$
0	0	0
0	1	1
1	0	1
1	1	1

Figure: Gate  $G_3$ :  $w_7 = w_5 \vee w_6$  in cleartext

## Garbling the wires

For each wire number  $w := 1, 2, 3, \dots$  and possible value on the wire ( $v := 0, 1$ )

- ▶ choose a random number called the "random encoding"  $e_w^v$ 
  - ▶ Thus  $e_5^1$  encodes the fact that "wire 5 has value 1"

The first party has thus a (secret) "translation table" for all possible values for all wires:

<i>wire</i>	<i>value</i>	<i>encoded – value</i>
$w_1$	0	$e_1^0$
$w_1$	1	$e_1^1$
$w_2$	0	$e_2^0$
$w_2$	1	$e_2^1$
...	...	...

**Figure:** Table: Encrypted Wire Values for all wires and all possible values

# Garbling a Circuit

$w_5$	$w_6$	$w_7$
$e_5^0$	$e_6^0$	$e_7^0$
$e_5^0$	$e_6^1$	$e_7^1$
$e_5^1$	$e_6^0$	$e_7^1$
$e_5^1$	$e_6^1$	$e_7^1$

(a) Gate  $G_3$  using encrypted wires

$$w_7 = w_5 \vee w_6$$

garbled gate
$h(e_5^1    e_6^0    g_3) \oplus e_7^1$
$h(e_5^0    e_6^0    g_3) \oplus e_7^0$
$h(e_5^0    e_6^1    g_3) \oplus e_7^1$
$h(e_5^1    e_6^1    g_3) \oplus e_7^1$

(b) Garbled  $G_3$   
( $w_7 = w_5 \vee w_6$ )

Figure: Garbled Computation table for  $G_3$

# Calculating a Garbled Circuit

## What is a garbled circuit?

It is a circuit, like one in cleartext:

- ▶ contains wires and gates
- ▶ contains tables representing the gates
  - ▶ but those tables are not "truth tables" (cleartext)
  - ▶ they are "Garbled Computation Tables" as in the previous slide
    - ▶ (rows have the form, say:  $h(e_5^0 || e_6^0 || g_3) \oplus e_7^0$ )

## How can you calculate a garbled circuit?

As for a normal circuit, you calculate each gate at a time in sequence

- ▶ but you work with garbled wire values, not with Booleans

Given, as input, the garbled wire values of a garbled gate

- ▶ In our example, given for instance  $e_5^0, e_6^1$
- ▶ It is easy to calculate  $h(e_5^0 || e_6^1 || g_3)$

# Calculating a Garbled Circuit

There is only one problem:

- ▶ the party who is calculating the garbled gate  $g_3$ 
  - ▶ has some "strange" values as inputs, say  $e_5^0$  and  $e_6^1$ 
    - ▶ but they are just some random looking numbers
  - ▶ he does not know that they are  $e_5^0$  and  $e_6^1$ 
    - ▶ they could be  $e_5^1$  and  $e_6^0$  (or any of the 4 combinations)
- ▶ thus, he does not know if he "is" in the row  $h(e_5^0 || e_6^1 || g_3) \oplus e_7^1$ 
  - ▶ or in another row, say  $h(e_5^1 || e_6^1 || g_3) \oplus e_7^1$ 
    - ▶ if he uses this row, he gets an incorrect answer for the garbled value of  $w_7$
- ▶ You need some **redundancy** / **markers** / **signals** (see class)

# Concepts: Non-transferable Proof; Interactive protocol

## An interactive protocol

Between 2 or more parties,

- ▶ requires both to be on-line simultaneously

Encrypting or signing a message is (typically) non-interactive:

- ▶ Say in secure email the sender is not necessarily on-line
  - ▶ when the email message is decrypted or the signature is verified

Challenge.response or ZKP (like Schnorr, see below)

- ▶ are typically interactive

# Concepts: Non-transferable Proof; Interactive protocol

## A proof is "non-transferable"

If it convinces "me" (the verifier)

- ▶ but the proof, no matter how I record it
  - ▶ will not convince other people
    - ▶ because it is easy for me to fake such proofs

It may be generated in

- ▶ an interactive or
- ▶ non-interactive protocol

# Concepts: Non-transferable Proof; Interactive protocol

- ▶ Example: a MAC (message authn code) is produced in
  - ▶ a non-interactive protocol
- ▶ the proof is non-transferrable
  - ▶ although it convinces me that it was generated
    - ▶ by the only other entity that knows the key

## Example

Key agreement is (typically) interactive

- ▶ but it is not a proof
  - ▶ you may have key agreements based on shared keys
  - ▶ or non-authenticated key agreements

# Interactive Zero-Knowledge Proofs

- ▶ An interactive proof
  - ▶ transfers the conviction to the verifier
    - ▶ that the claimed statement is true
  - ▶ but does not leak any further information
    - ▶ in particular, it does not create a transferable proof
    - ▶ that could convince anybody else
- ▶ The interactive proof is zero-knowledge
  - ▶ if the "transcript" of the proof
    - ▶ could have been constructed by anybody
- ▶ We say: anybody could simulate any protocol transcript
  - ▶ without interacting with the prover
- ▶ Of course, the transcript of the conversation
  - ▶ is not convincing for any other party

# Proof of knowledge / proof of possession

- ▶ Given a "public number"  $z$ 
  - ▶ s.t there is a "secret number"  $x$ 
    - ▶ in a particular relation to  $z$ :  $R(x, z)$
- ▶ Suppose  $P$  can be identified as the only entity
  - ▶ who knows the secret  $x$
- ▶ We want a method that allows  $P$  to
  - ▶ prove that he knows the secret  $x$ 
    - ▶ without disclosing *anything* about  $x$
    - ▶ except that  $R(x, z)$
- ▶ Example: Given
  - ▶ a group  $G = \langle g \rangle$ , of order  $p$ ,
  - ▶ a generator  $g$  and
  - ▶  $z \in G$  (say, the token of  $P$ )
- ▶  $P$  claims that he knows the secret  $x$  with  $z = g^x$
- ▶ A simple proof of this knowledge is Schnorr's identification scheme

# Schnorr's identification scheme

- ▶  $P$  claims to know  $x$  s.t  $g^x = z$
- ▶  $P$  chooses randomly  $k$

$$P \xrightarrow{t=g^k} V$$

$$P \xleftarrow{c} V$$

$$P \xrightarrow{r=cx+k} V$$

- ▶  $V$  accepts if  $g^r = tz^c$
- ▶ If  $P$  knows the secret  $x$ 
  - ▶ Then:  $g^x = z$ ,  $r = cx + k$ , and  $t = g^k$
  - ▶  $\Rightarrow g^r = g^k g^{cx} = t(g^x)^c = tz^c$ 
    - ▶ and therefore  $V$  accepts

# Properties of Schnorr's identification scheme

- ▶ Schnorr's identification scheme has 3 key properties:
- ▶ The proof presented to  $V$ 
  - ▶ cannot be used offline to demonstrate to anybody
    - ▶ that  $P$  (or anyone) knows the secret  $x$ :
  - ▶ in fact anybody could present a transcript
    - ▶ simulating having carried out a successful exchange
- ▶ It is secure
  - ▶ If  $V$  runs the protocol correctly
    - ▶ and  $P$  does not know the secret  $x$
  - ▶ Then the probability that
    - ▶  $P$  is able to answer the challenge  $c$  (message 2) correctly
    - ▶ is negligible
- ▶ The protocol discloses
  - ▶ absolutely no information about the secret
    - ▶ to  $V$
    - ▶ nor to anybody else

# Subgroups

- ▶ A subset  $G$  of the group  $\widehat{G}$  is a *subgroup* of  $\widehat{G}$ 
  - ▶ written as  $G \leq \widehat{G}$  iff  $G$  is itself a group with respect to the operation of  $\widehat{G}$

# Lagrange's Theorem: $H$ subgroup of $G \Rightarrow |H| \mid |G|$

- ▶ Proof: Let  $G$  be a group
  - ▶  $H$  be a subgroup of  $G$ . For each  $x \in G$  consider

$$xH := \{x \circ h \mid h \in H\}$$

- ▶ We claim that the sets  $xH$  are all of the size of  $H$  and form a partition of  $G$ 
  - ▶ It follows immediately that the size of  $H$  divides the size of  $G$

# Lagrange's Theorem: $H$ subgroup of $G \Rightarrow |H| \mid |G|$

- ▶ Two observations:
- ▶ For  $x, y \in G$  either  $xH$  and  $yH$  are equal or disjoint:
  - ▶ If  $xH \cap yH \neq \emptyset$  then there are  $h_1, h_2 \in H$  such that
    - ▶  $x \circ h_1 = y \circ h_2$  and thus for any  $h \in H$  it follows
    - ▶  $x \circ h = y \circ h_2 \circ h_1^{-1} \circ h \in yH$
  - ▶ Thus  $xH \subseteq yH$  and by symmetry  $xH = yH$
- ▶ The function

$$(x \circ \cdot) : H \rightarrow xH,$$

$$h \mapsto x \circ h$$

- ▶ is 1-1 ( $x \circ h_1 = x \circ h_2 \Rightarrow h_1 = h_2$ )
- ▶ cancelling  $x$ ) and onto (by definition of  $xH$ )

# Exercise on Lagrange's Theorem

- ▶ Let  $G$  be a group
  - ▶  $H$  be a subgroup of  $G$
  - ▶  $x \in G$  and  $xH := \{x \cdot h \mid h \in H\}$  as before
- ▶ For every  $x, y \in G$  let
  - ▶  $x \sim y :\Leftrightarrow xH = yH$
  - ▶  $x \sim y \Leftrightarrow x^{-1}y \in H$
- ▶  $\sim$  is an equivalence relation and the equivalence classes are precisely the sets  $xH$ 
  - ▶ Exercise: In the particular case of  $G = (\mathbb{Z}, +)$  and  $H = n\mathbb{Z}$  the subgroup of multiples of  $n$
  - ▶ calculate  $\sim$  and  $G/\sim$

# Cyclic Groups

- ▶ Starting from any element  $g$  in any group  $\widehat{G}$ 
  - ▶ consider the set of all powers of  $g \in \widehat{G}$
- ▶ This is a subgroup of  $\widehat{G}$ :
- ▶ it is denoted  $\langle g \rangle$  and called the *subgroup generated by  $g$*
- ▶ Note that this group  $\langle g \rangle$  is always commutative
  - ▶ even if  $\widehat{G}$  is not

# Subgroups, Cyclic Groups, Order of elements

- ▶ If  $\langle g \rangle$  is finite
  - ▶ its size is called *the order of  $g$*  (and *the order of the subgroup  $\langle g \rangle$* )
- ▶ Thus  $\text{ord}(g) = \text{ord}(\langle g \rangle) = |\langle g \rangle| = \min\{i \mid g^i = e\}$
- ▶ A group  $G$  is cyclic if it has an element  $g$  s.th
- ▶  $G = \langle g \rangle$
- ▶ Any finite cyclic group of order  $n$  is therefore of the form:
- ▶  $G =$ 

$$\{e, \underbrace{g}, \underbrace{g \circ g}, \underbrace{g \circ g \circ g}, \dots, \underbrace{g \circ g \circ g \circ g \circ \dots \circ g}_{(n-1 \text{ times})}\}$$
- ▶
 
$$= \{e, g, g^2, g^3, \dots, g^{n-1}\}$$
- ▶ Notice that any two cyclic groups of the same order are isomorphic
- ▶ In particular any cyclic groups is isomorphic to some "simple group" of the form  $(\mathbb{Z}_n, +_n)$  (next slide)

## A "simple" group

- ▶  $\mathbb{Z}_n = \{0, 1, 2, 3, \dots, n-1\}$  with  $+_n$  the **sum modulo  $n$**  as operation is a group for each  $n \in \mathbb{N}$
- ▶ The size of the group is  $n$
- ▶ This is an example of a "simple group" – that is a group where all interesting operations are easy to evaluate – but
  - ▶ as we will see
  - ▶ it is isomorphic to some *complex groups* where corresponding operations may be quite difficult
- ▶ It may sound strange that operations in one group  $G_1$  are simple and the "same" operations in an isomorphic group  $G_2$  are difficult
- ▶ but it is possible that in one direction the isomorphism
- ▶  $G_1 \rightarrow G_2$  is easy to calculate (say, using exponentiation)
  - ▶ while the reverse isomorphism  $G_2 \rightarrow G_1$  may be difficult or even infeasible to calculate (requiring the computation of a discrete logarithm)

# Examples of Groups

- ▶ The following are groups:
- ▶  $\mathbb{Z}_p^*$ : for some prime  $p$ 
  - ▶ is the set of elements
    - ▶  $\{1, 2, 3, \dots, p-1\}$  under the operation multiplication The size of the group is  $p-1$
- ▶  $\mathbb{Z}_7$ : consists of  $\{1, 2, 3, 4, 5, 6\}$ . For instance
  - ▶  $5 * 5 \equiv_7 25 \equiv_7 4$ 
    - ▶ The inverse can be derived similarly
  - ▶ for instance  $3^{-1}$  is represented by 5 since  $3 * 5 \equiv_7 15 \equiv_7 1$
- ▶  $G = \{1, 2, 4\}$  is a group under the operation multiplication modulo 7
- ▶  $G = \{1, 2, 4, 6\}$  is not a group under the operation multiplication modulo 7 because it does not obey the closure property:
  - ▶  $2 * 6 \pmod{7} \notin G$
- ▶ Elliptic Curve groups

- ▶ For  $a \in \mathbb{Z}_n^*$ , let the order of  $a$  be:

$$\text{ord}_{\mathbb{Z}_n^*}(a) := \min\{k \mid a^k \equiv_n 1\}$$

# Fermat's Theorem, Euler's Theorem

- ▶ Defs (recall): Order, generator
  - ▶ If  $G$  is finite, then
    - ▶  $\langle g \rangle := \{g^i : i \in \mathbb{Z}\}$
    - ▶ is also finite; the size is
  - ▶  $|\langle g \rangle| = \text{order}(g) := \min_i \{g^i = 1\}$
  - ▶ Thus  $\langle g \rangle = \{1, g, g^2, g^3, \dots, g^{\text{order}(g)-1}\}$
  - ▶ An element  $g \in G$  is called a *generator* of  $G$  if
  - ▶  $\langle g \rangle = G$  or equivalently, the order of  $g$  is  $|G|$

# Fermat's Theorem, Euler's Theorem

- ▶ Euler's Theorem
  - ▶ The order of every element  $g \in G$  divides  $|G|$
  - ▶ This follows from Lagrange's Theorem, since the size of the subgroup
  - ▶  $\langle g \rangle$  must divide the size of the group
- ▶ A simple consequence is:
  - ▶ Fermat's Theorem For every prime  $p$  and  $g \in \mathbb{N}$ ,
    - ▶  $g^{p-1} = 1 \pmod{p}$

## Application: generating random primes

- ▶ Suppose we want to generate a large random prime  $p$  of length 1024 bits (i.e.  $p \approx 2^{1024}$ )
- ▶ Choose a random integer  $p \in [2^{1024}, 2^{1025} - 1]$
- ▶ Test if  $2^{p-1} = 1$  in  $\mathbb{Z}_p$ 
  - ▶ If yes, done
  - ▶ If not, try another  $p$
- ▶ This is a simple algorithm, but not the best

$$\Pr[p \text{ passes the test but is not prime}] < 2^{-60}$$
